Abstract

The attachment theory suggests that the parental-child relationship is the building block for future relationship patterns and immediate security and comfort. A securely attached child will likely have healthy relationships as an adult, with better emotional awareness, empathy, and capacity to create long-term love relationships. On the other hand, insecurely attached children may go on to experience issues with attachment into adulthood, leading to relationship difficulties, emotional dysregulation, and greater risk of mental health difficulties such as personality disorders, anxiety, and depression. Additionally, it has been proven that the attachment system itself is also dynamic and changes depending on a wide range of relational and environmental circumstances. The type of attachment relationships can be influenced by a variety of factors, such as parenting style, societal context, cultural expectations, and even the occurrence of outside stressors like trauma or divorce. For instance, therapies that foster secure attachment can effectively decrease the negative impacts of early trauma and adversity and allow children to be resilient.

Keywords: Stable emotional bonding, Caregiver sensitivity, Social connections, Early growth and learning, Attachment assessment procedure

Introduction

"A long-term psychological relationship between human beings" is what Bowlby (1997) describes as the psychiatric concept "attachment." Attachment theory specifically emphasizes the significance of a child's emotional attachment to his/her main caregivers. If this attachment is broken or lost, it could impact the child's relationships in the future and his/her emotional and psychological health. A child's attachment style should only be evaluated by professionals who have undergone specialized training and certification. But all those who work with children need to know about attachment and how to enable parents and other carers to understand their children. This can be achieved through working directly with them or by referring the families to other suitable agencies. Eventually, this could result in better health and good outcomes for the caregivers and the child. The most robust and enduring is with the persons who have cared for them closely when they were small, though young people can develop relationships with multiple caregivers (Bowlby, 1997). Besides knowing and being sensitive to their needs, parents and other caregivers need to be able to take proper care of their newborn. Psychosocial growth happens as kids interact with other people, get connected, and learn to identify and regulate their feelings. The development of positive relationships, essential for socioemotional growth, is the single most significant social milestone of infancy. (Prizant et al., 1990) Attachment is a close relationship or bond with another person. Developmental psychologists want to know how neonates do this. To discover the answers to these questions, scientists Mary Ainsworth, John Bowlby, and Harry Harlow conducted experiments. Harlow used monkeys in several tests during the 1950s. He separated baby monkeys from their mothers. (Vicedo et al., 2009) Two surrogate mothers were presented to each animal. One was able to dispense milk and consisted of wire mesh. The other did not have milk, yet it was soft and made of fabric. (Robinson et al., 2012) In spite of the fact that it provided no sustenance, research shows that the monkeys preferred the soft, plush fabric monkey. The limitations of attachment theory have been criticized. While it's clear that secure relationships with caregivers affect human development throughout life, it's also

important to recall that Harlow, Bowlby, and Ainsworth primarily studied the role of mothers. One such criticism was from psychologist Michael Rutter, who argued the study of fathers and grandparents was excluded in attachment theory. As philosophers such as Lena Robinson point out, attachment theory was formulated based on Western concepts of "good parenting" and did not consider the diversity of parenting strategies employed in local cultures across the world. Finally, we notice that each of the interactions displayed in Table 1 is short and presents only a limited number of perspectives on the caregiver-child relationship. There is no longitudinal understanding of how that connection was formed. (Connell et al., 2013) Others have suggested that attachment varies across cultures, which Ainsworth's work did not address, and that a child's temperament might play a large role in attachment. The impact of early experiences and attachment on adulthood is of concern to researchers, as research indicates that those who have an insecure attachment style as a child will tend to be drawn to individuals who fulfill their expectations, even if they are abused. Importantly, our attachment styles are not fixed. We can break these insecure attachment expectations by developing secure attachments later in life. (Ein-Dor et al., 2010) To give a sound basis, teachers, carers, and networks of support can step in immediately with insecurely attached children, focusing on their internal sense of self-worth and external social relationships. (Webebbber et al., 2017)

Stable emotional bonding

Parents who embrace this believe a lot in their children and continually provide them with a safe environment. Taking an active role in the lives of their children gives them space and challenges them to be independent and self-reliant. They can explore, learn, succeed, and fail since they are safe, and in the process, they develop a strong, positive, independent, and unique sense of who they are. But there are some things you need to discuss. One of the main risk factors for the development of insecure attachment styles is inconsistency (in parents). Social relationships, friendships, and romantic relationships tend to be easier for individuals with a secure attachment style. They can sense and express their feelings, and they are aware of their needs. They don't overdo it and are direct and honest. Individuals who possess a secure attachment style in adulthood have high opinions of themselves. In order to feel special or worthy of love, they do not need approval. It does not mean, however, that they disregard or devalue emotional closeness. They just feel comfortable

both in a relationship and alone. These individuals have good opinions about other people, too. They do not feel the need to be envious or to question the motives of their loved ones since they tend to trust their relationships. They may receive tender gestures without becoming alarmed or bewildered. Those that possess a secure attachment style are normally courteous, tender, and warm. **Regulating Emotions:** Children who possess a secure attachment style are more capable of regulating and expressing their emotions. This leads to improved responses to stress and more stable mood patterns. Securely attached children have improved empathy and social skills and a more robust ability to form and maintain relationships. They also enhance their conflict resolution skills, which allows them to interact with peers and adults in more positive manners. **Self-Esteem:** Securely attached children feel a sense of identity and good self-esteem. This leads to higher confidence in their ability and judgment, and that increases psychological health overall. **Independence:** Secure attachment children are in a healthy middle ground of needing help and doing it for themselves. They show enhanced problem-solving skills when faced with challenges alone and greater confidence when experimenting with new situations. (Gillath et al., 2008)

Caregiver sensitivity

In addition, due to their sensitivity, parents' attachment styles in close relationships can influence their interactions with their children. The validation of the Parental Sensitivity Scale was the primary objective of this research. One of the components of parents' interactions with their children is their sensitivity to their signals and/or needs. This type of sensitivity can be demonstrated in any number of acts, but they must all have the requirement that they be appropriate, timely, and occur with warmth and tenderness. Different actions that qualify as parental responsiveness are outlined by this scale (Ainsworth et al., 1974; Edwards et al., 2010). The aim of this study was to validate the proposed measure's structure. Positive correlations between parental sensitivity, empathic care, and perspective taking were expected and explored to prove convergent validity. Negative correlations between anxiety, avoidance, and personal discomfort in close relationships were also explored to confirm discriminant validity. The study confirmed the validity, reliability, and unidimensional structure of the Parental Sensitivity Scale. This scale has been through various modifications to improve it. In order to enhance the model fit indices, two items were dropped. The scale measures how responsive parents are to their

children's cues. From birth through 18 months of age, the PRS can be a useful measure of parental interaction with their infants. In studies of influences on parental sensitivity, this scale may be useful for assessing parent-child interaction and for assessing subjective response. This measure may also be used as a subjective assessment of parental sensitivity in addition to an additional measure to provide complementarity to objective measures typically applied in laboratory or naturalistic observations of parent-child interaction. This would allow for the connection of subjective experience of sensitivity with its objective quantification. Parental responsiveness was related to greater empathy and perspective taking, as hypothesized. As indicated above, these two dimensions of other-oriented empathy are related to the ability to see things from others' points of view, sensitivity to their emotions, and awareness of others (Davis, 2004). We can conclude that even in cases when arousal is great and management is difficult, good emotional regulation is required for parental responsiveness as measured by the PRS (Eisenberg & Eggum, 2009). But since there was no relationship between lesser levels of personal distress and parental attentiveness as measured by the PRS, hypothesis two was partially confirmed. This type of empathy is to pay attention to others' bad feelings and focus on one's own experiences and self-oriented focus (Schreier et al., 2013). The absence of any apparent connection between PRS and personal distress suggests that parents are still taking care of their children's needs even when they are busy with their own emotions. (Tamis-LeMonda et al., 2014)

Social connections

Family relationships are the result of regular interaction among family members who are connected by blood. Friendships are willingly developed relationships with other people who need not be relatives or members of the same household. Dating, partnered, or married individuals belong to romantic relationships. They differ from familial and friendship relationships in that they are characterized by romantic love and often include greater levels of physical intimacy. Those who are close and share a non-sexual relationship are said to be in platonic relationships. Formal associations based on job-related activities are often termed professional relationships. The level of formality in interactions is dictated by the company's organizational structure and where the individual fits into it. We are social creatures by nature. We are all affected significantly by the kind of relationships we

have with other human beings in regards to our overall emotional, physical, and social well-being. Having interpersonal relationships can assist you in building a support system that will assist you through the challenges of life. A social bond or relationship between two or more people is referred to as an interpersonal relationship. It also defines the importance of such relationships and how to act in their aftermath. Any relationship requires good communication, but it's important to remember that good communication involves listening. Active listening is listening carefully to what the other is saying. (Orehek et al., 2018)

Early growth and learning

Children learn how to use language and symbolic thinking to manage their environment between the ages of two and seven. To transform the information they receive about the world around them, they learn to perform a range of mental activities using symbols, concepts, and ideas. Later childhood (ages seven to twelve) is when the rudiments of logic, which include categorizing concepts and comprehending time and numbers, begin to take shape. In addition to continuously improving during childhood, children's memory serves as the foundation for many other cognitive developments that occur throughout this time. Children display enhanced speed of retrieval and can hunt through their memory for data quicker and more efficiently as their long- and short-term memory grows. As children grow older, they become more self-aware of their own emotional states, characteristics, and abilities and develop empathy—the ability to appreciate the ideas, emotions, and perspectives of others. In turn, the acquisition of a moral sense is reliant on empathy and other social awareness. Human development is the process of change and progress from birth to maturity. Human development is by no means a straightforward, steady process. The distribution, composition, and organization of tissues change as a child grows. The head constitutes approximately the majority of tissues; cell division and, later, cell replacement are the predominant processes during the early phase of development. Consider the developmental milestones of the human brain. Learn more about the growth and development of the human brain. Discover how play is beneficial to human development. Learn more about the development advantages of play. Watch each video in this post. It's like creating a tapestry with a constantly evolving design. These fundamental strands constantly work against each other in a strongly regulated and controlled process,

each unwinding off its spool at its own speed. These control processes and the program driving the loom—a subject as yet poorly comprehended—are instrumental to the fundamental issues of development. (Walker et al., 2007)

Attachment assessment procedure

Fifty infants aged 12 to 18 months were tested by Waters (1978) with the SS method. 48 out of the 50 observed babies were placed in the same category individually at 18 months. One of the primary criticisms of Ainsworth's methodology is that it included only 100 middle-class Americans and their infants, so it is not likely that the results are generalizable to the entire population. Although John Bowlby is primarily linked with attachment theory, Mary Ainsworth's theory contributed substantially to the way attachment theory is talked about and applied today. The Strange Situation is Ainsworth's most famous contribution to attachment theory. Along with her colleague Sylvia Bell, Ainsworth created the Strange Situation, a test at Johns Hopkins that measured maternal-child attachment. When the mother of a child leaves them by themselves in a room, the "stranger" researcher watches as they respond. Due to the Strange Situation's continued high esteem as valid, many variations remain employed in contemporary research. Mary Ainsworth authored The Strange Situation in an attempt to test mother-infant attachment in a new environment. The initial work entailed researching children aged between 12 months and 18 months from 100 normal American families. The experimental design used was a playroom with several toys. The four criteria the children were split into three categories by Ainsworth and Bell were separation, fear of stranger, reunion behavior, and initiative to explore. The Strange Situation evaluates how a child explores the environment when the caregiver is around, when they are absent, and when a stranger is there. The attachment classification system, which distinguishes between dismissive and ambivalent attitudes on reunification with mothers, was originally created to address the first trial. Another way of saying this is that a child's behavior when they are separated from and then reunited with their mother tells us a lot about how they are attached to her. The basis for our existing classification of behaviors on the attachment spectrum is still this one. When the child was away from their caregiver, they showed signs of distress. When they came back, however, their parents stood by them and accorded them priority over the foreigner. (Van et al., 2015)

Conclusion

Our understanding of the importance of early emotional attachment in children to parents or primary caregivers has been advanced significantly through attachment theory. It brings focus to the child's social, emotional, and intellectual development, drawing attention to the important part that secure bonds have by noting their importance early on in infancy. Kids who are securely attached feel safe and trusted, and this gives them the confidence to venture out into the world and develop the essential skills for good relationships and emotional regulation in the future. In contrast, insecure attachments, brought about by inconsistent, neglectful, or emotionally unavailable behavior, can lead to issues with emotion management and the formation of future relationships that often extend into adulthood. Additionally, attachment theory is dynamic. It evolves in response to outside factors such as cultural factors, parenting styles, and economic conditions. Since attachment is dynamic, there are opportunities for interventions that can enhance or repair attachment styles, helping children overcome adversity and develop resilience.
